1 Introduction

Given the opportunity to review the design document and related source code of the `Tact`-based `UXLINK` smart contract, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About UXLINK

`UXLINK` aims to be the largest `Web3` social platform and infrastructure for users and developers to discover, distribute, and trade crypto assets in unique social and group-based manner. This specific audit focuses on its `UXLINK` token contract written in `Tact`. The basic information of the audited contract is as follows:

Table 1.1: Basic Information of The `UXLINK` Token Contract

Item	Description
Name	UXLINK Token
Type	Smart Contract
Platform	Tact
Audit Method	Whitebox
Latest Audit Report	July 25, 2024

In the following, we show the deployment address of the audited contract.

1.2 About PeckShield

PeckShield Inc. [9] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact \ Likelihood	*High*	*Medium*	*Low*
High	Critical	High	Medium
Medium	High	Medium	Low
Low	Medium	Low	Low

Likelihood

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [8]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would

Table 1.3: The Full List of Check Items

Category	Check Item
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy
	Money-Giving Bug
	Blackhole
	Unauthorized Self-Destruct
	Revert DoS
	Unchecked External Call
	Gasless Send
	Send Instead Of Transfer
	Costly Loop
	(Unsafe) Use Of Untrusted Libraries
	(Unsafe) Use Of Predictable Variables
	Transaction Ordering Dependence
	Deprecated Uses
Semantic Consistency Checks	Semantic Consistency Checks
Advanced DeFi Scrutiny	Business Logics Review
	Functionality Checks
	Authentication Management
	Access Control & Authorization
	Oracle Security
	Digital Asset Escrow

	Holistic Risk Management
Additional Recommendations	Avoiding Use of Variadic Byte Array
	Using Fixed Compiler Version
	Making Visibility Level Explicit
	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [7], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the `Tact`-based `UXLINK` smart contract. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	1	🟦
Low	2	🟦 🟦
Informational	0	
Total	3	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 2 low-severity vulnerabilities.

Table 2.1: Key UXLINK Token Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Medium	Incorrect TokenBurnNotfication Message Receiver in Jetton Trait	Business Logic	Resolved
PVE-002	Low	Revisited TokenTransfer Message in Jetton	Coding Practice	Resolved
PVE-003	Low	Trust Issue of Admin Keys	Security Features	Resolved

Besides recommending specific countermeasures to mitigate these issues, we also emphasize that it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Incorrect TokenBurnNotfication Message Receiver in Jetton Trait

- ID: PVE-001
- Severity: Medium
- Likelihood: Medium
- Impact: Medium

- Target: `Jetton`
- Category: Business Logic [6]
- CWE subcategory: CWE-841 [3]

Description

The audited `UXLINK` token has a `UxlinkJetton` master contract, which manages the overall information of the token, including the total supply and metadata. While reviewing the internal logic for total supply accounting, we notice an issue that stems from the incorrect implementation of the `TokenBurnNotfication` receiver.

To elaborate, we show below the implementation of the related `TokenBurnNotfication` receiver. This receiver validates the message sender to be the wallet owner of `msg.response_destination` (line 19), which should be the `msg.sender`. The incorrect validation may compromise the integrity of the storage state of `total_supply` (line 20).

```
18    receive(msg: TokenBurnNotification) {
19        self.requireSenderAsWalletOwner(msg.response_destination!!);       // Check
              wallet
20        self.total_supply = self.total_supply - msg.amount; // Update supply
21        if (msg.response_destination != null) { // Cashback
22            send(SendParameters{
23                to: msg.response_destination!!,
24                value: 0,
25                bounce: false,
26                mode: SendRemainingValue,
27                body: TokenExcesses{ query_id: msg.query_id }.toCell()
28            });
29        }
```

```
    }
```

Listing 3.1: The `Jetton::TokenBurnNotification` Receiver

Recommendation Revise the above routine to properly validate the intended caller.

Status The issue has been fixed according to the above suggestion.

3.2 Revisited TokenTransfer Message in Jetton

- ID: PVE-002
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: `Jetton`
- Category: Coding Practices [5]
- CWE subcategory: CWE-563 [2]

Description

The audited `UXLINK` token implements the `Jetton` trait, which has defined a number of messages. One specific one is `TokenTransfer` with the purpose of transferring funds. Our analysis shows one specific field of this message can be better renamed.

In particular, we show below the definition of this message type `TokenTransfer`. We notice a field named `sender`, which implies the message sender. However, the field is used to indicate the recipient of this token transfer. With that, we suggest to rename it to `recipient` or simply `to`.

```
message(0xf8a7ea5) TokenTransfer {
    query_id: Int as uint64;
    amount: Int as coins;
    sender: Address;
    response_destination: Address?;
    custom_payload: Cell?;
    forward_ton_amount: Int as coins;
    forward_payload: Slice as remaining;
}
```

Listing 3.2: The Message Type of `TokenTransfer`

Recommendation Redefine the above `TokenTransfer` message type to ensure the member field is not misleading.

Status The issue has been fixed according to the above suggestion.

3.3 Trust Issue of Admin Keys

- ID: PVE-003
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Target: `UxlinkJetton`
- Category: Security Features [4]
- CWE subcategory: CWE-287 [1]

Description

In the `UXLINK` contract, there is a privileged account, i.e., `owner`, which plays a critical role in governing and regulating the token contract (e.g., minting new tokens into circulation and adjusting the token content). Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and their related privileged accesses in current contracts.

```
    receive(msg: Mint) { // 0xfc708bd2
        let ctx: Context = context();
        require(ctx.sender == self.owner, "Not owner");
        require(self.mintable, "Not mintable");
        require(self.total_supply + msg.amount <= self.max_supply, "Max supply exceeded"
            );
        self.mint(msg.receiver, msg.amount, self.owner); // (to, amount,
            response_destination)
    }

    receive(msg: UpdateOwnerAddress) {
        require(sender() == self.owner, "Not owner");
        self.owner = msg.address;
        self.reply("Owner updated".asComment());
    }
```

Listing 3.3: Example Privileged Operations in the `UxlinkJetton` Contract

If the privileged admins are managed by a plain `EOA` account, this may be worrisome and pose counter-party risk to the exchange users. A multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed `DAO`. In the meantime, a timelock-based mechanism can also be considered as mitigation.

Recommendation Promptly transfer the privileged account to the intended `DAO`-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been mitigated with a multi-sig account to manage the `owner` account.

4 Conclusion

In this audit, we have analyzed the design and implementation of the `Tact`-based `UXLINK` contract, which aims to be the largest `Web3` social platform and infrastructure for users and developers to discover, distribute, and trade crypto assets in unique social and group-based manner. This specific audit focuses on its related `UXLINK` token contract written in `Tact`. During the audit, we notice that the current code base is well organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
