1 Introduction

Given the opportunity to review the design document and related source code of the UXLINK Reward Pool smart contract, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About UXLINK Reward Pool

UXLINK aims to be the largest Web3 social platform and infrastructure for users and developers to discover, distribute, and trade crypto assets in unique social and group-based manner. This specific audit focuses on its staking contract to reward staking users. The basic information of the audited contract is as follows:

ltem	Description
Name	UXLINK Reward Pool
Туре	Ethereum Smart Contract
Platform	Solidity
Audit Method	Whitebox
Latest Audit Report	December 12, 2024

Table 1.1:	Basic Information of	The UXLINK Reward	Pool Contract
------------	----------------------	-------------------	---------------

In the following, we show the deployment address of the audited contract.

• https://sepolia.arbiscan.io/address/0x14462F5501fFF2842Af14c2721596De3Ba4f502e

And here are the new deployment addresses of the audited contract after all fixes have been checked in:

1.2 About PeckShield

PeckShield Inc. [7] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

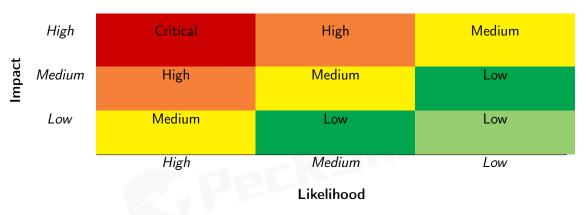

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [6]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Category	Check Item	
	Constructor Mismatch	
	Ownership Takeover	
	Redundant Fallback Function	
	Overflows & Underflows	
	Reentrancy	
	Money-Giving Bug	
	Blackhole	
	Unauthorized Self-Destruct	
Basic Coding Bugs	Revert DoS	
Dasic Counig Dugs	Unchecked External Call	
	Gasless Send	
	Send Instead Of Transfer	
	Costly Loop	
	(Unsafe) Use Of Untrusted Libraries	
	(Unsafe) Use Of Predictable Variables	
	Transaction Ordering Dependence	
	Deprecated Uses	
Semantic Consistency Checks	Semantic Consistency Checks	
	Business Logics Review	
	Functionality Checks	
	Authentication Management	
	Access Control & Authorization	
	Oracle Security	
Advanced DeFi Scrutiny	Digital Asset Escrow	
	Kill-Switch Mechanism	
	Operation Trails & Event Generation	
	ERC20 Idiosyncrasies Handling	
	Frontend-Contract Integration	
	Deployment Consistency	
	Holistic Risk Management	
	Avoiding Use of Variadic Byte Array	
	Using Fixed Compiler Version	
Additional Recommendations	Making Visibility Level Explicit	
	Making Type Inference Explicit	
	Adhering To Function Declaration Strictly	
	Following Other Best Practices	

Table 1.3:	The Full	List of	Check	ltems
------------	----------	---------	-------	-------

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- <u>Basic Coding Bugs</u>: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- <u>Advanced DeFi Scrutiny</u>: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- <u>Additional Recommendations</u>: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [5], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Category	Summary	
Configuration	Weaknesses in this category are typically introduced during	
	the configuration of the software.	
Data Processing Issues	Weaknesses in this category are typically found in functional-	
	ity that processes data.	
Numeric Errors	Weaknesses in this category are related to improper calcula-	
	tion or conversion of numbers.	
Security Features	Weaknesses in this category are concerned with topics like	
	authentication, access control, confidentiality, cryptography,	
	and privilege management. (Software security is not security software.)	
Time and State	Weaknesses in this category are related to the improper man-	
	agement of time and state in an environment that supports	
	simultaneous or near-simultaneous computation by multiple	
	systems, processes, or threads.	
Error Conditions,	Weaknesses in this category include weaknesses that occur if	
Return Values,	a function does not generate the correct return/status code,	
Status Codes	or if the application does not handle all possible return/status	
	codes that could be generated by a function.	
Resource Management	Weaknesses in this category are related to improper manage-	
	ment of system resources.	
Behavioral Issues	Weaknesses in this category are related to unexpected behav-	
	iors from code that an application uses.	
Business Logics	Weaknesses in this category identify some of the underlying	
	problems that commonly allow attackers to manipulate the	
	business logic of an application. Errors in business logic can	
	be devastating to an entire application.	
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used	
Annual Development	for initialization and breakdown.	
Arguments and Parameters	Weaknesses in this category are related to improper use of	
Furnessian lasure	arguments or parameters within function calls.	
Expression Issues	Weaknesses in this category are related to incorrectly written	
Coding Prostings	expressions within code.	
Coding Practices	Weaknesses in this category are related to coding practices	
	that are deemed unsafe and increase the chances that an ex-	
	ploitable vulnerability will be present in the application. They	
	may not directly introduce a vulnerability, but indicate the	
	product has not been carefully developed or maintained.	

2 Findings

2.1 Summary

Here is a summary of our findings after analyzing the UXLINK Reward Pool implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings		
Critical	0		
High	0		
Medium	2		
Low	0		
Informational	1		
Total	3		

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 2 medium-severity vulnerabilities and 1 informational recommendation.

ID	Severity	Title	Category	Status
PVE-001	Medium	Possible Blocked Withdrawal Under Insuf-	Coding Practice	Resolved
		ficient Surplus		
PVE-002	Informational	Accommodation of Non-ERC20-	Business Logic	Resolved
		Compliant Tokens		
PVE-003	Medium	Trust Issue of Admin Keys	Security Features	Mitigated

Table 2.1: Key UXLINK Reward Pool Audit Findings

Besides recommending specific countermeasures to mitigate these issues, we also emphasize that it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Possible Blocked Withdrawal Under Insufficient Surplus

- ID: PVE-001
- Severity: Medium
- Likelihood: Medium
- Impact: Medium
- Description
- The UXLINKTokenRewardPoolMultiple contract supports standard staking features and allows users to stake and unstake their funds. While reviewing current unstaking logic, we notice an issue that may result in unstaking failure.

To elaborate, we show below the implementation of the related withdraw() routine as well as the associated checkNextEpoch modifier. We notice the associated modifier has a requirement, i.e., require(poolSurplusReward >= nextCycleReward) (line 177), which may revert the withdraw operation if current surplus reward is not able to support the next cycle reward. This revert unfortunately blocks users funds from being withdrawn.

```
312
         function withdraw(
313
             uint256 amount,
314
             uint256 positionID
315
         ) external updateReward(msg.sender) checkNextEpoch nonReentrant {
316
             require(
317
                 withdrawOpened,
318
                 "Have not opened"
319
             );
320
             require(
321
                 amount > MIN_WITHDRAW_AMOUNT,
322
                 "Withdraw amount must be greater than MIN_WITHDRAW_AMOUNT"
323
             );
324
325
```

• Target: UXLINKTokenRewardPoolMultiple

• Category: Business Logic [4]

CWE subcategory: CWE-841 [2]

```
173
        modifier checkNextEpoch() {
174
             if (block.timestamp >= periodFinish) {
175
                 curCycleReward = nextCycleReward;
176
                 require(
177
                     poolSurplusReward >= nextCycleReward,
178
                     "poolSurplusReward is not enough"
179
                 );
180
                 poolSurplusReward = poolSurplusReward - nextCycleReward;
181
                 curCycleStartTime = block.timestamp;
182
                 periodFinish = block.timestamp + (nextDuration);
183
                 cycleTimes++;
184
                 lastUpdateTime = curCycleStartTime;
185
                 rewardRate = curCycleReward / (nextDuration);
186
                 totalReward = totalReward + (curCycleReward);
187
                 emit StartNewEpoch(curCycleReward, nextDuration);
188
             }
189
             _;
190
```

Listing 3.2: UXLINKTokenRewardPoolMultiple::checkNextEpoch()

Recommendation Properly revise the above routines to ensure the user staked funds can be reliably withdrawn in all cases.

Status The issue has been resolved by following the above suggestion.

3.2 Accommodation of Non-ERC20-Compliant Tokens

- ID: PVE-002
- Severity: Informational
- Likelihood: N/A
- Impact: N/A

- Target: Multiple Contracts
- Category: Business Logic [4]
- CWE subcategory: CWE-841 [2]

Description

Though there is a standardized ERC-20 specification, many token contracts may not strictly follow the specification or have additional functionalities beyond the specification. In the following, we examine the transfer() routine and related idiosyncrasies from current widely-used token contracts.

In particular, we use the popular token, i.e., ZRX, as our example. We show the related code snippet below. On its entry of transfer(), there is a check, i.e., if (balances[msg.sender] >= _value && balances[_to] + _value >= balances[_to]). If the check fails, it returns false. However, the transaction still proceeds successfully without being reverted. This is not compliant with the ERC20 standard and may cause issues if not handled properly. Specifically, the ERC20 standard specifies the

following: "Transfers _ value amount of tokens to address _ to, and MUST fire the Transfer event. The function SHOULD throw if the message caller's account balance does not have enough tokens to spend."

```
64
        function transfer(address _to, uint _value) returns (bool) {
65
            //Default assumes total
Supply can't be over max (2^256 - 1).
66
            if (balances [msg.sender] >= value && balances [ to] + value >= balances [ to]) {
67
                balances [msg.sender] -= value;
                balances [ to] += value;
68
69
                Transfer(msg.sender, _to, _value);
70
                return true;
71
            } else { return false; }
72
       }
74
        function transferFrom(address _from, address _to, uint _value) returns (bool) {
75
            if (balances[_from] >= _value && allowed[_from][msg.sender] >= _value &&
                balances[_to] + _value >= balances[_to]) {
76
                balances [ to] += value;
77
                balances [ from ] -= value;
78
                allowed [ from ] [msg. sender ] -= value;
                Transfer(_from, _to, _value);
79
80
                return true;
81
            } else { return false; }
82
```

Listing 3.3: ZRX::transfer()/transferFrom()

Because of that, a normal call to transfer() is suggested to use the safe version, i.e., safeTransfer (), In essence, it is a wrapper around ERC20 operations that may either throw on failure or return false without reverts. Moreover, the safe version also supports tokens that return no value (and instead revert or throw on failure). Note that non-reverting calls are assumed to be successful. Similarly, there is a safe version of approve()/transferFrom() as well, i.e., safeApprove()/safeTransferFrom().

In the following, we show the safeTokenTransfer() routine in the UXLINKTokenRewardPoolMultiple contract. If the USDT token is supported as rewardToken, the unsafe version of IERC20(rewardToken).transfer(_to, tokenBalance) (line 442) may revert as there is no return value in the USDT token contract's transferFrom() implementation (but the IERC20 interface expects a return value)!

```
438
        function safeTokenTransfer(address _to, uint256 _amount) internal {
439
            require(rewardToken != address(0x0), "No harvest began");
440
            uint256 tokenBalance = IERC20(rewardToken).balanceOf(address(this));
441
            if (_amount > tokenBalance) {
442
                 IERC20(rewardToken).transfer(_to, tokenBalance);
443
            } else {
444
                IERC20(rewardToken).transfer(_to, _amount);
445
            }
446
```

Listing 3.4: UXLINKTokenRewardPoolMultiple::safeTokenTransfer()

Recommendation Accommodate the above-mentioned idiosyncrasy about ERC20-related approve()/transfer()/transferFrom().

Status This issue has been resolved by following the above suggestion.

3.3 Trust Issue of Admin Keys

- ID: PVE-003
- Severity: Medium
- Likelihood: Medium
- Impact: Medium

- Target: UXLINKTokenRewardPoolMultiple
- Category: Security Features [3]
- CWE subcategory: CWE-287 [1]

Description

In the UXLINKTokenRewardPoolMultiple contract, there is a privileged account, i.e., manager, which plays a critical role in governing and regulating the staking-wide operations (e.g., parameter setting and reward token adjustment). It also has the privilege to affect the flow of assets managed by this protocol. Our analysis shows that the privileged account needs to be scrutinized. In the following, we examine the privileged account and their related privileged accesses in current contracts.

```
125
         function notifyMintAmount(uint256 addNextReward) external onlyManager {
126
             uint256 balanceBefore = IERC20(rewardToken).balanceOf(address(this));
127
             IERC20(rewardToken).safeTransferFrom(
128
                 msg.sender,
129
                 address(this),
130
                 addNextReward
131
             );
132
             uint256 balanceEnd = IERC20(rewardToken).balanceOf(address(this));
133
134
             poolSurplusReward = poolSurplusReward + (balanceEnd - balanceBefore);
135
             emit AddNextCycleReward(poolSurplusReward);
136
        }
137
138
         function setNextCycleReward(
139
             uint256 _nextCycleReward,
140
             uint256 _nextDuration
141
         ) external onlyManager {
142
             nextCycleReward = _nextCycleReward;
143
             nextDuration = _nextDuration;
144
             emit SetRewardConfig(nextCycleReward, nextDuration);
145
        }
146
147
         function setStakeTimeRatio(
148
             uint256[] memory _stakeTimeRatio
149
         ) external onlyManager {
150
             require( _stakeTimeRatio.length<=36, "stakeTimeRatio length is invalid!");</pre>
```

```
151
             stakeTimeRatio = _stakeTimeRatio;
152
             emit SetStakeTimeRatio(_stakeTimeRatio);
        }
153
154
        function setPunishRate(uint256 _punishRate) external onlyManager {
155
156
             punishRate = _punishRate;
157
             emit SetPunishRate(_punishRate);
158
        }
159
        function setWithdrawOpened(bool _opened) external onlyManager {
160
161
             withdrawOpened = _opened;
162
```

Listing 3.5: Example Privileged Operations in the UXLINKTokenRewardPoolMultiple Contract

If the privileged admins are managed by a plain EOA account, this may be worrisome and pose counter-party risk to the exchange users. A multi-sig account could greatly alleviate this concern, though it is still far from perfect. Specifically, a better approach is to eliminate the administration key concern by transferring the role to a community-governed DAO. In the meantime, a timelock-based mechanism can also be considered as mitigation.

Recommendation Promptly transfer the privileged account to the intended DAD-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status This issue has been mitigated with a multi-sig account to take the role of the manager.

4 Conclusion

In this audit, we have analyzed the design and implementation of the staking reward contract in UXLINK, which aims to be the largest Web3 social platform and infrastructure for users and developers to discover, distribute, and trade crypto assets in unique social and group-based manner. This audit focuses on the staking contract to reward staking users. During the audit, we notice that the current code base is well organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
